

Method Details

The same compact memory is trained by multiview primitive evidence, reconstructed into foundation-feature spaces, and calibrated into stable object support.

(a) Multiview Primitive Registration

Training only: multiview evidence is distilled into compact codes; no VPR cache is read at inference.

(b) Query-Conditioned Feature Reconstruction

A low-dimensional memory reconstructs features only when a query/task needs them.

(c) Support-Calibrated Selection

The calibration acts on support, not just feature cosine, reducing fragmented or low-visibility selections.
